TECHNICAL NOTE 3831

TABULATION OF MASS-FLOW PARAMETERS FOR USE IN DESIGN OF TURBOMACHINE

BLADE ROWS FOR RATIOS OF SPECIFIC HEATS OF 1.3 AND 1.4

By Warren J. Whitney

SUMMARY

Mass-flow tables for ratios of specific heats γ of 1.3 and 1.4 are presented for the entire range of critical velocity ratio. The tables enable a quick and accurate determination of the integrated average specific mass flow across a region where the end-point velocities are known, commensurate with the assumptions that the total state is constant and the static pressure varies linearly between the two velocities. A numerical example is included to illustrate the use of the tables. All quantities are in nondimensional form and are tabulated against critical velocity ratio. The tables include specific-mass-flow parameter and ratio of static to total pressure.

INTRODUCTION

In a comprehensive turbine blading design procedure, the blade surface velocities are determined at two or three radial sections by a method such as that of reference 1. The blade surfaces and average velocity level are then adjusted until the blade passage satisfies the design mass-flow-handling requirement, and the blade surface velocity variations are reasonably close to the prescribed velocity variation. Thus, it is necessary to determine the integrated mass flow at various locations throughout the blade passage. The two assumptions that have frequently been used in turbine blading design procedure to determine the integrated mass flow are: (1) The total state of the fluid is constant along a potential line (or channel orthogonal), and (2) the static pressure varies linearly along the orthogonal between known (or computed) velocities. In order to facilitate mass-flow integrations commensurate with these assumptions, tables I and II were computed.

In addition to the quantity used to obtain average integrated mass-flow parameter, the point values of mass-flow parameter and static- to total-pressure ratio are tabulated against critical velocity ratio.

Although the specific-mass-flow parameter could be obtained from reference 2 as the product of the density ratio and the critical velocity ratio, the quantities in the reference are tabulated against Mach number, and it would be required to extrapolate in many cases for a desired critical velocity ratio.

SYMBOLS

$$A \quad \text{value of integral} - \int_{\frac{p}{p'} = 1.0}^{\frac{p}{p'}} \left(\frac{\rho V}{\rho' V_{cr}} \right) d\left(\frac{p}{p'}\right)$$

p absolute static pressure, lb/sq ft

p' absolute total pressure, lb/sq ft

v gas velocity, ft/sec

V_{cr} velocity of sound at Mach number of 1.0, ft/sec

γ ratio of specific heats

ρ gas density based on static temperature and static pressure, lb/cu ft

ρ' gas density based on total temperature and total pressure, lb/cu ft

CONSTRUCTION OF TABLES

The density ratio and pressure ratio were expressed as functions of the critical velocity ratio as follows:

$$\frac{\rho}{\rho'} = \left[1 - \frac{\gamma - 1}{\gamma + 1} \left(\frac{V}{V_{cr}} \right)^2 \right]^{\frac{1}{\gamma-1}}$$

$$\frac{p}{p'} = \left[1 - \frac{\gamma - 1}{\gamma + 1} \left(\frac{V}{V_{cr}} \right)^2 \right]^{\frac{\gamma}{\gamma-1}}$$

The pressure ratio, density ratio, and specific-mass-flow parameter were evaluated over a range of critical velocity ratio from 0 to the maximum

value (given by $\left(\frac{r+1}{r-1}\right)^{1/2}$) for r of 1.3 and 1.4. The integral A was determined by a step-by-step trapezoidal integration between successive V/V_{cr} values that differed by 0.001. Each elemental area, dA , was combined with the previous total so that the A value represents the cumulative area for any particular critical velocity ratio.

The variation of specific-mass-flow parameter with static- to total-pressure ratio is shown in figure 1. Included in the figure for reference is an auxiliary abscissa of critical velocity ratio that is necessarily nonlinear, because a linear static-pressure variation was specified. This figure shows that the average integrated mass flow (commensurate with the assumptions used herein) between known critical velocity ratios of approximately 0.5 and 0.95 would be the area, bcde, divided by the abscissa be. However, the A values represent the cumulative area under the curve of $\rho V/\rho' V_{cr}$ as a function of the ratio of static to total pressure p/p' . Thus, the difference in A values for the two critical velocity ratios is equal to the area bcde. Although the quantity A can be integrated directly, it was convenient to use a point-by-point integration, since it was desired to obtain p/p' and $\rho V/\rho' V_{cr}$ for the various V/V_{cr} values. Furthermore, for a value of r for which $2/(r-1)$ does not equal a whole number, direct integration results in a power series, and a large number of terms must be used to obtain the desired accuracy.

USE OF TABLES

The tables can be used for a moving (or rotating) blade row as well as for a stationary blade row. In the case of a rotating blade row, the velocity V and the total-state quantities ρ' and V_{cr} must be evaluated relative to the moving blade row. The following numerical example is included to illustrate the use of the tables. A sketch of a typical turbine blade flow channel is shown in figure 2. It is assumed that the velocities have been determined for all the orthogonals at the two surfaces (e.g., points c and d, fig. 2) by the stream-filament method (ref. 1). It is desired to obtain the average integrated mass flow for the various orthogonals. Referring to figure 2, the following critical velocity ratios are assumed for the orthogonal cd:

Point c (suction surface): $V/V_{cr} = 0.996$

Point d (pressure surface): $V/V_{cr} = 0.558$

The integrated average mass flow is determined from table I ($r = 1.4$) as follows:

4187

CB-1 back

Point	c	d
V/V_{cr}	0.996	0.558
A (from table I)	.2332614	.0577960
$(p/p') \text{ (from table I)}$.5312402	.8298491

The average integrated specific mass flow for the orthogonal cd is equal to $\left(\frac{\Delta A}{-\Delta \frac{p}{p'}} \right)_{c-d}$ or 0.5876094. The actual weight flow can then be obtained by multiplying by the total-state quantity, $\rho' V_{cr}$. Thus, the mass flow per unit depth would be $0.5876094 \times (\rho' V_{cr}) \times cd$.
